What are Nitrates?

Nitrates (NO\textsubscript{3}) are a vital source of nitrogen (N) for plants. When nitrogen fertilizers are used in the soil, nitrates may be carried by rain, irrigation and other surface waters through the soil into ground water. Human and animal wastes can also add to nitrates in ground water. High nitrates in drinking water may also suggest there are other contaminants.

Who is at risk from high nitrates in drinking water?

Nitrate levels at or above the level set by the Environmental Protection Agency (EPA) have been known to cause a blood disorder that can be fatal in infants under six months of age called "blue-baby" syndrome (methemoglobinemia). Babies with blue-baby syndrome have reduced oxygen-carrying capacity in their blood. It is difficult to know how often blue-baby syndrome occurs in California because it is not required to be tracked and reported.

Others at risk from excess nitrates in drinking water are:

- Pregnant women
- Individuals with reduced gastric acidity, and
- Individuals with a hereditary lack of methemoglobin reductase.

Testing recommendations

The EPA has set the Maximum Contaminant Level (MCL) of nitrate as nitrogen (NO\textsubscript{3}) at 45 mg/L (or 45 parts per million) for the safety of drinking water. If you get your drinking water from a well, it is recommended that you test your water for nitrates at least once every 3 years. This is highly recommended if there is an infant or someone is pregnant in the household.

What can you do if you have high nitrates in your drinking water?

If your drinking water sample tested above the MCL for nitrates and you or someone else in your home is at risk of developing health problems due to high nitrates, you should not drink the water. Find a different water supply such as bottled water until you can find a more permanent solution.

There is no simple way to remove all nitrates from your water. Identifying and treating nitrate contamination is the best course of action. Boiling water will in fact increase the levels of nitrates. Reverse osmosis, ion exchange and distillation units could provide home treatment for removing nitrates from water. Activated carbon and other simple filters do not remove nitrates to any significant degree. Home treatment units, such as point of use and point of entry devices, are generally not recommended as a long-term solution to assure nitrate-free water for infant use. Your only long-term option may be to find a new source of water.
